

BSA AI Agent

POC Scope & Next Steps

Overview

As part of this POC we will demonstrate a Business System Analyst AI Agent that helps BSA leads get their work done faster by auto-generating BRDs and Jira stories from meeting transcripts and supporting documents.

This solution enables your team to:

- Eliminate manual BRD creation effort
- Improve consistency and completeness of requirements
- Accelerate story readiness for sprint planning
- Continuously learn and improve from user feedback

POC Scope – What we will Demonstrate

End-to-End Workflow Automation

1. Requirement Intake (Within Jira)

- BSAs upload meeting transcripts, notes, and supporting documents into a Jira ticket - AI Workbench
- No change to existing workflow or tools

2. AI-Powered BRD Generation

- AI agent consolidates inputs, builds context, and generates a **structured, review-ready BRD**
- Output is directly attached back to the same Jira ticket

3. Human Review & Control

- BSA reviews, refines, and approves the BRD
- Ensures governance and accuracy remain with your team

4. Automated Story Creation

- AI decomposes approved BRD into:
 - Epics
 - User stories
 - Acceptance criteria
- Delivered directly into Jira, ready for sprint planning

5. Iterative Enhancement (Real-World Use Case)

- New inputs can be added at any time
- AI updates BRD and Stories
- AI highlights scope changes

6. Conversational Interface (Demo Capability)

- Chat-based interaction of the similar to Jira flow

Note: For the scope of demo we have considered using Jira platform workflow to interact with AI agent. This can be changed later easily based how we decide to implement the user experience.

The following diagram illustrates the end-to-end journey from requirement collection through to well defined user story

Generate Story

6

AI Agent Creates Epic & Stories

- Analyze and update BRD and Jira Story.
- Provides insight on story deviation or scope creep summary as part of comments.
- Provides the summary of new changes added.

Story Ready

Future Vision – Beyond POC

Once validated, this evolves into a **fully intelligent BSA ecosystem**:

Continuous Learning: Feedback-in-Loop Iterations

Capture edits and corrections that BSAs make to generated BRDs and use them to continuously improve output quality. When the agent consistently gets something wrong, the system learns from the corrections and adjusts its approach — ensuring each BRD is better than the last.

Customizable BRD and Story Templates

Provide BSAs with an intuitive interface to define and customise BRD structures and story templates. Different teams and domains can maintain their own templates, ensuring the AI agent produces output that matches each team's specific format and requirements.

Interactive Context Accumulation and Gap Resolution

Enhance the Jira sidebar chatbot to support deeper conversations with the AI agent. BSAs can iteratively add context across multiple sessions, resolve identified gaps through targeted Q&A, and refine stories conversationally — all within the Jira interface with full context preserved between sessions.

Integrated Knowledge Base

Feed the AI agent with knowledge from your existing systems — Confluence pages, Zuora and Salesforce documentation, internal wikis, and other reference material. The agent uses this background knowledge alongside uploaded documents to produce more accurate and context-aware BRDs and stories.

Process Flow Diagram Generation

Automatically generate visual process flow diagrams alongside the BRD, showing current-state or target-state workflows. These diagrams provide an additional layer of documentation that helps teams quickly understand system flows and business processes.

Comprehensive Knowledge Retrieval (RAG)

Build a full retrieval system that connects to Confluence, Jira history, existing BRDs, ERDs, object models, and vendor documentation. The agent searches this knowledge base automatically during BRD generation, ensuring requirements are informed by the complete picture of your systems and their history.

Channel Strategy — Slack, Teams, or Dedicated Chatbot

Evaluate and implement the optimal channel for BSA-agent interaction beyond the Jira sidebar. Options include Slack integration, Microsoft Teams bots, or a dedicated web-based chatbot — chosen based on where your teams are most productive.

Observability and Cost Tracking

Full visibility into the AI agent's operations: what inputs it received, how it processed them, what output it produced, and what it cost. When a BRD doesn't meet expectations, the team can trace exactly where the issue occurred — whether in document parsing, context assembly, or the generation step — and address it directly.

QA Test Case and Automation Generation

Extend the AI agent pipeline with a QA agent that reads approved stories and automatically generates structured test cases — covering happy paths, edge cases, and negative scenarios. These test cases can then be converted into executable test automation scripts in your team's preferred framework.

Continuous Learning from BSA Corrections

When a BSA edits a generated BRD or story, the system captures what was changed and why. Over time, these corrections reveal patterns that are used to improve the AI agent's prompts and templates — resulting in progressively better output that requires less manual adjustment.

Story Dependency Mapping

When stories are generated, the agent could suggest likely dependencies between them — for example, flagging that a backend API story should be completed before the frontend story that consumes it. These would be presented as suggestions for the BSA and scrum lead to confirm during grooming, helping with sprint sequencing.
